Product Idea – Individual Understanding & Alignment

Product / Idea Name: TBD – Personal Document & Government Services Assistant
Prepared By: Sree
Purpose: Capture my understanding from the product discussion for comparison and alignment with the rest of the team.

---

1. My Understanding in One Paragraph

The idea is to build a **centralized, secure personal document repository and intelligent application assistant for Indian users**.

Today, when people in India need services from government departments, banks, passport offices, RTO/DMV offices, registration offices, mandal/panchayat offices, educational institutions, or similar organizations, they frequently need to complete forms and provide copies of multiple supporting documents.

The required documents vary depending on the service. A person may be asked for Aadhaar, PAN, voter ID, birth certificate, educational certificates, property documents, employment letters, pay slips, photographs, or other records.

Many people—particularly older adults, people in villages, and users who are not comfortable with technology—find these processes difficult. As a result, they may depend on brokers or intermediaries who charge ₹1,000–₹5,000 or more to help complete forms and navigate the process.

Our proposed product would allow users to securely maintain their important documents in one location. When they need a particular service, they select the service or application they want to complete. The system identifies the required information and supporting documents, extracts the necessary information from the user's stored documents, populates the appropriate application form, attaches the required supporting documents, and produces an application package that the user can review, print/sign where necessary, and submit.

The long-term objective is to make complicated administrative processes much easier for ordinary citizens.

---

2. What Problem Are We Solving?

Main Problem

People repeatedly provide the same personal information and documents to different organizations while completing government, banking, registration, licensing, educational, employment, and other administrative processes.

The process is often:

- confusing,
- repetitive,
- paper/document intensive,
- difficult for non-technical users,
- dependent on knowing which documents are required,
- dependent on having those documents available at the right time,
- prone to mistakes when filling forms,
- and sometimes dependent on brokers/intermediaries.

Who Has This Problem?

Potential users include:

- ordinary Indian citizens,
- senior citizens,
- rural and village populations,
- people with limited technology experience,
- people unfamiliar with government processes,
- people who do not frequently use computers,
- families managing documents for multiple family members,
- and potentially anyone who regularly completes government, banking or administrative forms.

How Are They Solving It Today?

People currently:

- maintain physical copies of documents,
- keep photocopies,
- search WhatsApp/email/phones for scanned documents,
- visit photocopy/printing shops,
- manually complete forms,
- repeatedly enter the same information,
- ask relatives or friends for help,

- visit internet/cyber service centers,
- or use brokers/agents who complete the process for a fee.

Why Is the Current Solution Not Good Enough?

There is no simple workflow that connects:

My Documents → My Information → Service Requirements → Completed Application

The user currently has to understand all four pieces themselves.

---

3. Who Is the Target User?

Primary User

An Indian citizen who needs help completing government, banking, licensing, registration, educational, employment, or other administrative applications.

Particularly Valuable For

- Senior citizens
- Rural users
- Non-tech-savvy users
- People who frequently depend on brokers
- Families managing documents for parents or children
- People who struggle with English or complicated forms

Other Potential Stakeholders

Future stakeholders could include:

- banks,
- government departments,
- service centers,
- panchayat/mandal offices,
- document/printing centers,
- authorized agents,
- employers,
- educational institutions,
- and other organizations that receive applications.

These institutional integrations are **not necessarily part of the initial product** and need further discussion.

---

4. What Is the Product Supposed to Do?

My understanding of the intended experience is:

1. User creates an account/profile.
2. User uploads important personal documents such as:
    - Aadhaar
    - PAN
    - Voter ID
    - Birth certificate
    - Driving licence
    - Passport
    - Property/registration documents
    - Educational certificates
    - Employment letters
    - Pay slips
    - and other commonly required documents.
3. The system securely stores and organizes these documents.
4. The system extracts important information from the documents and builds a structured user profile.
5. The user selects the service they need.
   For example:
   Bank → Open Savings Account
6. The system determines:
    - which application/form is required,
    - what information needs to be entered,
    - and which supporting documents are required.
7. The system retrieves the required information from the user's profile/documents.
8. The application form is automatically populated.
9. The appropriate supporting documents are selected from the user's repository.
10. The user reviews the information and confirms that it is correct.
11. The system creates an application package containing:

Completed Form + Required Supporting Documents

12. The user can download/print the package, sign it where required, and submit it to the appropriate organization.

---

5. Most Important Features

Must Have for V1

1. Secure user account/profile
2. Secure document upload and storage
3. Document classification
4. OCR/data extraction from uploaded documents
5. Structured personal profile created from documents
6. Service/application catalog
7. Document requirement mapping for each supported service
8. Automatic form filling
9. Automatic supporting-document selection
10. User review and correction before finalization
11. Generate/download/print completed application package

Good to Have Later

1. Direct electronic submission to organizations
2. Aadhaar/PAN or other government integrations where legally and technically permitted
3. Application status tracking
4. Mobile application
5. Voice interaction
6. Indian-language support
7. AI conversational assistant
8. Family document management
9. Expiry reminders
10. Missing-document notifications
11. Authorized representative/family assistance
12. Organization/API integrations

---

6. What Role Does AI Play?

AI could potentially make the product significantly easier to use.

AI Could:

- identify uploaded document types,
- extract information from documents,
- understand different application forms,
- map profile information to form fields,
- determine which stored documents satisfy application requirements,
- identify missing information,
- identify missing documents,
- explain confusing questions in simple language,
- translate/explain forms in local languages,
- detect inconsistencies between documents,
- and guide users through the application process conversationally.

AI Should NOT:

AI should not silently make important decisions or submit information without the user's knowledge.

For example, if the PAN document contains one address and Aadhaar contains another, the system should not simply decide which one is correct.

It should tell the user:

"We found two different addresses. Which address should be used for this application?"

Human-in-the-Loop

The user should remain in control.

A likely workflow is:

AI prepares → User reviews → User corrects/confirms → System generates final application

For sensitive or legally significant information, explicit user confirmation should be required.

---

7. What Makes This Product Different?

The product is not simply cloud document storage.

Products such as Google Drive or other storage systems can store documents, but the proposed value is turning those documents into **actionable applications**.

The key concept is:

> **Don't just store my documents. Use my documents to help me get things done.**

The product connects:

Personal Document Vault

↓

Structured Citizen Profile

↓

Service Requirements

↓

Intelligent Form Filling

↓

Required Supporting Documents

↓

Application Package

That workflow could be the primary differentiator.

---

8. How Do We Make Money?

Not sufficiently discussed yet.

Possible models that the team could evaluate later include:

☐ Subscription
☐ Freemium
☐ Pay per completed application
☐ Family subscription
☐ B2B partnerships
☐ Service-center licensing

☐ Enterprise/institutional integration
☐ Other

This should remain an **open decision** until we understand the target customer and economics better.

---

9. What Does Success Look Like?

The product is successful if an ordinary user who previously needed help from another person or broker can independently complete an application correctly.

A strong success scenario would be:

> A user selects a service, the system already has most of the information and documents required, and within a few minutes produces a nearly complete application package requiring only review, confirmation, signature, and submission.

Potential metrics:

- Applications successfully prepared
- Percentage of fields automatically populated
- Time saved per application
- Number of documents automatically identified
- Reduction in missing-document situations
- Percentage of applications completed without outside assistance
- Repeat users
- User satisfaction
- Cost saved compared with intermediaries

---

10. What I Believe We Already Agreed On

Based on my understanding of today's discussion:

1. People face unnecessary difficulty completing administrative forms and assembling supporting documents.
2. Users repeatedly provide the same documents and personal information.
3. Non-tech-savvy users face greater difficulty.
4. Many users depend on intermediaries/brokers.

5. Users should have a centralized repository for important personal documents.
6. The system should reuse stored information instead of requiring users to repeatedly enter it.
7. Users should be able to select the service/application they need.
8. The system should populate the relevant form.
9. The system should identify and attach appropriate supporting documents.
10. The user should ultimately be able to produce a completed application package.

These points should be compared with everyone's individual understanding before being considered final team decisions.

---

11. What I Think Is Still Undecided

The team needs alignment on several important questions:

1. Is this primarily a **document vault**, **form-filling platform**, **AI citizen assistant**, or all three?
2. Are we initially targeting government services only, or government + banks + private organizations?
3. Which services will V1 support?
4. Will users only download/print applications, or will the system eventually submit applications electronically?
5. How will we keep application forms and document requirements current?
6. Will we integrate directly with government systems?
7. What is our business model?
8. Mobile-first, web-first, or both?
9. Will family members be able to manage documents for parents/children?
10. Which Indian languages will be supported?
11. What level of AI automation is appropriate?
12. How will we handle highly sensitive identity documents securely?

---

12. Assumptions I Am Making

1. I am assuming users will be willing to securely store important personal documents with the platform.
2. I am assuming we can legally store and process the relevant documents with appropriate consent, security, privacy controls, and regulatory compliance.

3. I am assuming application forms and their requirements can be obtained and maintained accurately.
4. I am assuming information can be reliably extracted from commonly used Indian documents.
5. I am assuming users will review and approve generated applications before using them.
6. I am assuming the first version does not require direct integration with every government department.
7. I am assuming the initial product can provide value simply by producing a completed application package.

These assumptions need validation.

---

13. Things I Did Not Understand Clearly / Need Team Alignment

1. What exactly constitutes V1?
2. Which government/service processes should we support first?
3. Who is our first target customer?
4. Are we replacing brokers or enabling them?
5. Are government integrations required?
6. How will the product make money?
7. How much automation should AI perform?
8. How will document/form templates be maintained?

---

14. Concerns / Risks

Product

The idea can become extremely broad because potentially thousands of services and forms exist.

We need a narrow initial use case.

Technology

Forms can change frequently and different organizations may use different formats and requirements.

Document extraction must also be highly accurate.

AI

AI cannot be allowed to invent information when completing official forms.

Every populated field should ideally have traceability to its source, for example:

Date of Birth → extracted from Aadhaar

or

Employer → extracted from Employment Letter

Privacy & Security

This is potentially the largest concern.

The platform could contain extremely sensitive personal information, including:

- Aadhaar
- PAN
- passports
- birth certificates
- financial documents
- employment information
- property documents
- educational records

Security, encryption, consent, access control, retention/deletion, auditability, breach response, and applicable Indian privacy/identity rules need to be treated as core product requirements rather than afterthoughts.

Business

We still need to determine who pays and why they would pay.

---

15. My Version of the MVP

I would keep the MVP deliberately small.

Instead of trying to support hundreds of government services, select approximately **3–5 common use cases**.

For example:

- One banking application
- One government certificate/service
- One RTO/licensing-related application
- One local government application

The exact services should be selected after research.

MVP Should Demonstrate

Upload Documents

↓

Extract & Build Profile

↓

Choose Service

↓

Identify Requirements

↓

Populate Form

↓

Select Supporting Documents

↓

User Review

↓

Generate Application Package

If we can demonstrate this workflow reliably for a handful of real-world services, we have proven the core product concept.

MVP Should NOT Initially Try To

- integrate with every government department,
- support every Indian state,
- automate submission everywhere,
- eliminate all human review,
- or support hundreds of application types.

---

16. Example User Story

As a citizen who needs to apply for a service,

I want to select the service I need and have the system automatically use my stored personal information and documents to prepare the application,

So that I don't have to understand complicated forms, repeatedly enter the same information, search for documents, or depend on a broker to prepare the application.

---

17. Biggest Questions the Team Must Answer Next

1. **Who exactly is our first target user?**
2. **What are the first 3–5 services we will support?**
3. **What is our core product boundary?**
4. **How will we securely store and process sensitive documents?**
5. **How will service requirements/forms be maintained and updated?**
6. **What is automated by AI versus deterministic software?**
7. **What requires explicit user confirmation?**
8. **What regulatory/privacy requirements apply?**
9. **What is our revenue/business model?**
10. **What would prove that people actually want this product before we invest heavily in building it?**

Final 60-Second Summary

In one sentence, what are we building?

A secure intelligent platform that stores a citizen's important documents and uses them to automatically prepare forms and supporting-document packages for government, banking, and other administrative services.

For whom?

Initially, Indian citizens—particularly people who find complex administrative processes difficult or currently depend on others to complete them.

What problem does it solve?

It eliminates much of the repeated document gathering, photocopying, data entry, form confusion, and dependence on intermediaries involved in accessing everyday services.

What is the most important capability?

Turning a user's existing documents and information into a **ready-to-review application package for a selected service**.

Why would someone use it?

Because instead of asking:

"What form do I need? What documents do I need? Where are my documents? What do I enter here?"

the user should eventually be able to say:

"I need this service."

And the platform handles most of the preparation.
